

MOs for Period 2 Homonuclear Diatomic Molecules

- Only the valence AOs are considered – **one 2s** orbital and **three 2p** orbitals for each atom
- When two atoms approach each other:
 - The **2s** orbitals overlap to form two **σ MOs**, bonding (σ_{2s}) and antibonding (σ_{2s}^*) (as in H_2)
 - The **2p** orbitals directed along the internuclear axis overlap to form **two σ MOs**, bonding (σ_{2p}) and antibonding (σ_{2p}^*)
 - The **2p** orbitals perpendicular to the internuclear axis overlap to form **four π MOs**, **two bonding** (π_{2p}) and **two antibonding** (π_{2p}^*)

Example: N_2

Total # of valence e^- s

$$\rightarrow 5+5=10$$

\rightarrow place 10 e^- s on the lowest energy MOs

Electron configuration \rightarrow

$$BO = (8 - 2)/2 = 3$$

\rightarrow Consistent with the Lewis structure ($:N \equiv N:$)

Example: O₂

Total # of valence e⁻s → 6+6=12

→ 12 e⁻s on the lowest energy MOs

Electron configuration →

O₂: (σ_{2s})²(σ_{2s}^{*})²(σ_{2p})²(π_{2p})⁴(π_{2p}^{*})²

BO = (8 - 4)/2 = 2

→The electron configuration of O₂ contains **two unpaired** electrons on the π_{2p}^{*} MOs (Hund's rule)

– Inconsistent with the Lewis structure (:O=O:)

→Explains the **paramagnetic properties** of O₂

Example: Be₂

Total # of valence e⁻s → 2+2=4

⇒ place 4 e⁻s on the lowest energy MOs

Electron configuration → (σ_{2s})²(σ_{2s}^{*})²

BO = (2 - 2)/2 = 0 → (the molecule is unstable)

Example: Ne₂

Total # of valence e⁻s → 8+8=16

⇒ place 16 e⁻s on the lowest energy MOs

Electron configuration →

(σ_{2s})²(σ_{2s}^{*})²(σ_{2p})²(π_{2p})⁴(π_{2p}^{*})⁴(σ_{2p}^{*})²

BO = (8 - 8)/2 = 0 → (the molecule is unstable)

Valence electron configuration	(σ _{2s}) ² (σ _{2s} [*]) ² (π _{2p}) ²	(σ _{2s}) ² (σ _{2s} [*]) ² (π _{2p}) ⁴	(σ _{2s}) ² (σ _{2s} [*]) ² (π _{2p}) ⁴ (σ _{2p}) ²	(σ _{2s}) ² (σ _{2s} [*]) ² (σ _{2p}) ² (π _{2p}) ⁴ (π _{2p} [*]) ²	(σ _{2s}) ² (σ _{2s} [*]) ² (σ _{2p}) ² (π _{2p}) ⁴ (π _{2p} [*]) ⁴	

Example:

Predict the electron configuration, BO and bond strength of the N₂⁻ ion

Total # of valence e⁻s → 5+5+1=11

⇒ place 11 e⁻s on the lowest energy MOs

Electron configuration →

(σ_{2s})²(σ_{2s}^{*})²(π_{2p})⁴(σ_{2p})²(π_{2p}^{*})¹

BO = (8 - 3)/2 = 2.5

→The ion exists (BO > 0)

→The bond is weaker than that in N₂ (lower bond order 2.5 < 3)

MOs for Heteronuclear Diatomic Molecules

- Diagrams are asymmetric since the AOs of the two atoms have different energies

Example: NO

Total # of valence e⁻s → 5+6=11

⇒ place 11 e⁻s on the lowest energy MOs

Electron configuration →

$$BO = (8 - 3)/2 = 2.5$$

→ Contains **one unpaired e⁻**

→ Explains the existence of **odd electron molecules** (radicals)

MOs in Polyatomic Species

- The general approach is similar
- The MOs are built by more than two AOs
 - Linear Combinations of Atomic Orbitals (LCAO)
- The MOs are spread over the entire molecule
 - Delocalization** of electrons
 - Explains the existence of **electron deficient molecules** (on average less than two electrons may be binding two atoms → multi-center bonds)

Example: B₂H₆

The H-bridges are based on a three-center MO holding 2e⁻s

- Delocalization** and **multi-center bonds** eliminate the need of resonance structures used by the Lewis's and VB models

Example: O₃

Resonance structures:
