## Ionic Equilibria in Aqueous Systems

### 19.1 Acid-Base Buffers

- Resist changes in $\boldsymbol{p H}$ upon addition of acids $\left(\mathrm{H}^{+}\right)$ or bases ( $\mathrm{OH}^{-}$)

## The Buffer Action

- Buffer solutions consist of to components
- Acid component - reacts with added bases $\left(\mathrm{OH}^{-}\right)$
- Base component - reacts with added acids $\left(\mathrm{H}^{+}\right)$
- The two components must be a conjugate acidbase pair
- The two components must be present in high concentrations

## The $\boldsymbol{p H}$ of a Buffer

- For a weak acid buffer (HA/A-), $A^{-}$can be supplied in solution by means of the salt, MA $\mathrm{MA} \rightarrow \mathrm{M}^{+}+\mathrm{A}^{-}$
- HA and $\mathrm{A}^{-}$reach equilibrium

$$
\mathrm{HA}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{A}^{-}
$$

$$
K_{a}=\frac{\left[\mathrm{H}_{3} \mathbf{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]} \Rightarrow\left[\mathrm{H}_{3} \mathbf{O}^{+}\right]=K_{a} \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}
$$

$\Rightarrow$ The $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\boldsymbol{p} \boldsymbol{H}$ depend on the ratio $[\mathbf{H A}] /\left[\mathbf{A}^{-}\right]$ $\rightarrow$ If [ HA ] and $\left[\mathrm{A}^{-}\right]$are relatively large, adding small amounts of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$changes the ratio only slightly, so $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx$ constant
$\rightarrow$ Take a $-\log ()$ of $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{a}\left(C_{a} / C_{b}\right)$
$-\log \left[\mathbf{H}_{3} \mathbf{O}^{+}\right]=-\log \boldsymbol{K}_{a}-\log \frac{\boldsymbol{C}_{a}}{\boldsymbol{C}_{b}}=-\log \boldsymbol{K}_{a}+\log \frac{\boldsymbol{C}_{b}}{\boldsymbol{C}_{a}}$ $\Rightarrow p H=p K_{a}+\log \frac{C_{b}}{C_{a}} \quad \begin{aligned} & \text { Henderson-Hasselbalch } \\ & \text { Equation }\end{aligned}$
$\rightarrow$ The equation is valid only if $C_{a}$ and $C_{b}$ are large enough so that the assumptions [HA] $\approx C_{a}$ and [A-] $\approx C_{b}$ are justified; If not, [HA] and [A ${ }^{-}$] must be used $\rightarrow$ Works if $\boldsymbol{C}_{a}>\mathbf{1 0 0} \times \boldsymbol{K}_{a}$ and $\boldsymbol{C}_{b}>\mathbf{1 0 0} \times \boldsymbol{K}_{b}$ $\rightarrow$ If $\boldsymbol{C}_{\boldsymbol{a}}=\boldsymbol{C}_{\boldsymbol{b}}, \log \left(C_{a} / C_{b}\right)=0$ and $\boldsymbol{p} \boldsymbol{H}=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}$ $\Rightarrow$ If $\boldsymbol{C}_{\boldsymbol{a}}$ and $\boldsymbol{C}_{\boldsymbol{b}}$ are comparable, the $\boldsymbol{p} \boldsymbol{H}$ of the buffer is close to the $\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}$ of the acid component
$>$ Weak acid buffer - a solution of the weak acid,
HA , and its conjugate base, $\mathrm{A}^{-}\left(\mathrm{HF} / \mathrm{F}^{-}, \ldots\right.$ )
$>$ Add $\mathrm{H}_{3} \mathrm{O}^{+}($acid $) \rightarrow\left(\mathrm{A}^{-}\right.$consumes the added $\left.\mathrm{H}_{3} \mathrm{O}^{+}\right)$ $\mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{A}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HA}$
$>$ Add $\mathrm{OH}^{-}$(base) $\rightarrow$ (HA consumes the added $\mathrm{OH}^{-}$) $\mathrm{OH}^{-}+\mathrm{HA} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{A}^{-}$
$>$ Weak base buffer - a solution of the weak base, B, and its conjugate acid, $\mathrm{HB}^{+}\left(\mathrm{NH}_{4}{ }^{+} / \mathrm{NH}_{3}, \ldots\right)$
$>$ Add $\mathrm{H}_{3} \mathrm{O}^{+}($acid $) \rightarrow\left(\mathrm{B}\right.$ consumes the added $\left.\mathrm{H}_{3} \mathrm{O}^{+}\right)$
$\mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{B} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HB}^{+}$
$>$ Add $\mathrm{OH}^{-}($base $) \rightarrow\left(\mathrm{HB}^{+}\right.$consumes the added $\left.\mathrm{OH}^{-}\right)$ $\mathrm{OH}^{-}+\mathrm{HB}^{+} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{B}$
$\Rightarrow$ The addition of $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$changes the relative amounts of the buffer components ( $\mathrm{HA} / \mathrm{A}^{-}$or $\mathrm{HB}^{+} / \mathrm{B}$ )

- Both HA and A- react with water

1. $\mathrm{HA}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{A}^{-}$
2. $\mathrm{A}^{-}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{OH}^{-}+\mathrm{HA}$
$\rightarrow$ Both equilibria are shifted to the left, so the amounts of HA and A- produced are often very small compared to the total concentrations, $C_{H A}$ and $C_{A^{-}}$ $\Rightarrow$ Assume that $[\mathrm{HA}]_{2}$ and $\left[\mathrm{A}^{-}\right]_{1} \ll C_{H A}$ and $C_{A^{-}}$ $[\mathrm{HA}]=C_{H A}-\left[\mathrm{A}^{-}\right]_{1}+[\mathrm{HA}]_{2} \approx C_{H A}=\boldsymbol{C}_{\boldsymbol{a}}$ $\left[\mathrm{A}^{-}\right]=C_{A^{-}}-\left[\mathrm{HA}_{2}+\left[\mathrm{A}^{-}\right]_{1} \approx C_{A^{-}}=\boldsymbol{C}_{\boldsymbol{b}}\right.$
$\rightarrow \boldsymbol{C}_{a}$ and $\boldsymbol{C}_{\boldsymbol{b}}$ - total concentrations of the acid and base components of the buffer

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{a} \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]} \quad \Rightarrow \quad\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{a} \frac{C_{a}}{C_{b}}
$$

Example: What is the $\boldsymbol{p H}$ of a buffer that is $\mathbf{0 . 5 0}$ $\mathbf{M}$ in HF and $\mathbf{0 . 5 0} \mathbf{M}$ in KF ? $\left(\boldsymbol{K}_{\boldsymbol{a}}=6.8 \times 10^{-4}\right.$ for HF$)$

1. Use the Hend.-Hass. Eq. (HF - acid; F- - base)

$$
\boldsymbol{C}_{\boldsymbol{a}}=0.50 \quad \boldsymbol{C}_{\boldsymbol{b}}=0.50
$$

$\boldsymbol{p} \boldsymbol{H}=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}+\log (0.50 / 0.50)=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}+\log (1)=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}+0$
$\boldsymbol{p} \boldsymbol{H}=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}=-\log \left(6.8 \times 10^{-4}\right)=\mathbf{3 . 1 7}$
2. Or use an ice table

| [] | $\mathrm{HF}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{F}^{-}$ |  |  | $K_{a}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{F}^{-}\right]}{[\mathrm{HF}]}=$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $i$ | 0.50 | 0 | 0.50 |  |  |
| c | -x | + $x$ | + $x$ | $x(0.50+x)$ | $x(0.50)$ |
| $e$ | 0.50-x | $x$ | $0.50+x$ | (0.50-x) | (0.50) |
| $\boldsymbol{x}=\boldsymbol{K}_{\boldsymbol{a}}=6.8 \times 10^{-4}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \Rightarrow \boldsymbol{p} \boldsymbol{H}=-\log \left(6.8 \times 10^{-4}\right)=\mathbf{3 . 1 7}$ |  |  |  |  |  |

Example: For $\mathbf{1 . 0} \mathbf{L}$ of the same buffer, calculate the $\boldsymbol{p} \boldsymbol{H}$ after the addition of $\mathbf{5 . 0} \mathbf{~ m L} \mathbf{2 . 0} \mathbf{M ~ H C l}$.
$\rightarrow \mathrm{HCl}$ is a strong acid and converts to $\mathrm{H}_{3} \mathrm{O}^{+}$which reacts with $\mathrm{F}^{-}$from the buffer
$\rightarrow$ Calculate the starting moles of HF and $\mathrm{F}^{-}$in the buffer and the added moles of $\mathrm{H}_{3} \mathrm{O}^{+}$from HCl
$\mathrm{HF} \quad \rightarrow 1.0 \mathrm{~L} \times 0.50 \mathrm{~mol} / \mathrm{L}=\mathbf{0 . 5 0} \mathbf{~ m o l}$ $\mathrm{F}^{-} \quad \rightarrow 1.0 \mathrm{~L} \times 0.50 \mathrm{~mol} / \mathrm{L}=\mathbf{0 . 5 0} \mathbf{~ m o l}$ $\mathrm{H}_{3} \mathrm{O}^{+} \rightarrow 0.0050 \mathrm{~L} \times 2.0 \mathrm{~mol} / \mathrm{L}=\mathbf{0 . 0 1 0} \mathbf{~ m o l}$ $\rightarrow$ Use an "srf" table (starting, reacted, final) to calculate the final moles of HF and $\mathrm{F}^{-}$

- The addition of strong acids or bases to unbuffered solutions has a much greater effect on $\boldsymbol{p H}$

Example: Calculate the $\boldsymbol{p} \boldsymbol{H}$ after the addition of $5.0 \mathbf{m L} 2.0 \mathrm{M} \mathrm{HCl}$ to 1.0 L of pure water .
$\rightarrow$ The $\boldsymbol{p} \boldsymbol{H}$ of pure water is $\mathbf{7 . 0 0}$
$\rightarrow$ After addition of the strong acid HCl :

$$
\begin{aligned}
& {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{0.0050 \mathrm{~L} \times \frac{2.0 \mathrm{~mol}}{1 \mathrm{~L}}}{(1.0+0.0050) \mathrm{L}}=0.010 \mathrm{M}} \\
& p H=-\log (0.010)=2.00
\end{aligned}
$$

$\Rightarrow$ The $\boldsymbol{p H}$ is reduced by 5.00 pH -units (a much larger change compared to the buffered solution)

## Preparing Buffers

$>$ Choose the conjugate acid-base pair (select a pair with an acid component having $\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}$ close to the desired buffer $\boldsymbol{p H}$ )
$>$ Calculate the ratio of $\boldsymbol{C}_{b} / \boldsymbol{C}_{a}$ needed to achieve the desired buffer $\boldsymbol{p} \boldsymbol{H}$ (use the Hend.-Hass. Eq.)
$>$ Determine the buffer concentration and the amounts of the two components to be mixed
$>$ Mix the components and adjust the $\mathbf{p H}$ (final pH may be slightly off and can be adjusted by adding strong acid or base)
$>$ Buffers can also be prepared by partial neutralization of weak acids (or bases) with strong bases (or acids) (Ex: $\mathrm{HF}+\mathrm{KOH} \rightarrow \mathrm{KF}+\mathrm{H}_{2} \mathrm{O}$; If only half of the HF is converted to $\mathrm{KF} \rightarrow$ buffer)

| $\begin{aligned} & \text { n } \\ & 0 \\ & \vdots \end{aligned}$ | [] | $\mathrm{F}^{-}+\mathrm{H}_{3} \mathrm{O}^{+} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HF}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $s$ | 0.50 | 0.010 | - | 0.50 |
|  | $r$ | -0.010 | -0.010 | - | +0.010 |
|  | $f$ | 0.49 | 0.00 | - | 0.51 |

$\rightarrow$ Use the Hend.-Hass. Eq. (HF - acid; F- - base)
$\rightarrow$ Since the acid an base components of the buffer are in the same volume, the ratio of the concentrations is the same as the ratio of the moles $\rightarrow \boldsymbol{C}_{b} / \boldsymbol{C}_{\boldsymbol{a}}=\boldsymbol{n}_{b} / \boldsymbol{n}_{\boldsymbol{a}}$

$$
\begin{aligned}
p H & =p K_{a}+\log \frac{n_{b}}{n_{a}}=-\log \left(6.8 \times 10^{-4}\right)+\log \frac{0.49}{0.51} \\
& =3.17+(-0.02)=3.15
\end{aligned}
$$

$\Rightarrow$ The $\boldsymbol{p H}$ is reduced by only 0.02 pH -units

## Buffer Capacity and Buffer Range

- Buffer capacity (BC) - a measure of the ability of the buffer to resist $\boldsymbol{p} \boldsymbol{H}$ changes $-\boldsymbol{B C}$ is higher for more concentrated buffers $\uparrow \uparrow C_{a}$ and $C_{b} \Rightarrow \uparrow \uparrow$ Buffer capacity $-\boldsymbol{B C}$ is higher for buffers with similar component concentrations ( $\boldsymbol{B C}$ is highest when $\boldsymbol{C}_{\boldsymbol{a}}=\boldsymbol{C}_{\boldsymbol{b}}$ )
- Buffer range ( $\boldsymbol{B R}$ ) - buffers act most efficiently when $\boldsymbol{C}_{b} / \boldsymbol{C}_{\boldsymbol{a}}$ is between $\mathbf{0 . 1}$ and $\mathbf{1 0}$ $\begin{aligned} & p H=p K_{a}+\log (0.1)=p K_{a}-1 \\ & p H=p K_{a}+\log (10)=p K_{a}+1\end{aligned} \Rightarrow B R=p K_{a} \pm 1$

Example: How many moles of $\mathrm{NH}_{4} \mathrm{Cl}$ must be added to $\mathbf{1 . 0} \mathbf{L}$ of $\mathbf{0 . 2 0} \mathbf{M ~ N H}_{3}$ solution to get a buffer with $\boldsymbol{p} \boldsymbol{H}=\mathbf{9 . 3 5}$ ? $\left(\boldsymbol{K}_{\boldsymbol{b}}=\mathbf{1 . 8} \times \mathbf{1 0}^{-5}\right.$ for $\left.\mathrm{NH}_{3}\right)$
$\rightarrow$ Conjugate pair $\mathbf{N H}_{4}{ }^{+} / \mathbf{N H}_{3}$

### 19.2 Acid-Base Titration Curves

- Titration curves - plots of $\boldsymbol{p H}$ versus the volume of titrant added during titration
- Equivalence point (E) - a point along the course of the titration at which the acid and the base are present in equivalent (stoichiometric) amounts and consume each other completely
- Typically, the $\boldsymbol{p} \boldsymbol{H}$ changes sharply at the E-point and this fact is used in the detection of the E-point
- The titration is actually stopped at the end point
- Ideally, the end point should be at the equivalence point, but in practice they can differ slightly due to imperfect detection of the E-point
$>$ The indicator is a weak B-L acid

$$
\mathrm{HIn}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{In}^{-}
$$

- The acid form of the indicator, HIn, and its conjugate base, $\mathrm{In}^{-}$, have different colors
- If $[\mathbf{H I n}] /\left[\mathbf{I n}^{n}\right]>10$, the solution has the color of the acid form, HIn
- If $[\mathbf{H I n}] /\left[\mathbf{I n}^{-}\right]<\mathbf{0 . 1}$, the solution has the color of the base form, $\mathrm{In}^{-}$
$\Rightarrow$ The color change is within $\mathbf{0 . 1}<[\mathbf{H I n}] /[\mathbf{I n}]<\mathbf{1 0}$
$\Rightarrow$ The ratio $[\mathbf{H I n}] /[\mathbf{I n}]$ depends on $\left[\mathbf{H}_{3} \mathbf{O}^{+}\right]$

$$
K_{I n}=\frac{\left[\mathrm{H}_{3} \mathbf{O}^{+}\right]\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]} \Rightarrow \frac{[\mathrm{HIn}]}{\left[\mathrm{In}^{-}\right]}=\frac{\left[\mathrm{H}_{3} \mathbf{O}^{+}\right]}{K_{I n}}
$$

## Acid-Base Indicators

- Indicators - used to estimate the $\boldsymbol{p} \boldsymbol{H}$ of solutions and to detect the E-point in titrations
- Weak organic acids with general formula HIn
- Exhibit different colors at different $\boldsymbol{p H}$ values
- The colors are quite intense so only small amounts are needed for detection
- Indicator rage - a relatively narrow $\boldsymbol{p H}$ range over which the indicator changes color
- If the $\mathbf{E}$-point is within (or close to) the indicator range, the indicator changes color very close to $\mathbf{E}$
$\Rightarrow$ The $\boldsymbol{p} \boldsymbol{H}$ at the $\mathbf{E}$-point must be known for the proper selection of an indicator

## Strong Acid-Strong Base Titration Curves

$>$ Strong acids and bases are completely converted to $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$in water solns.
$\Rightarrow$ The net ionic equation of the titration is:

$$
\mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-} \rightarrow 2 \mathrm{H}_{2} \mathrm{O}
$$

$\Rightarrow$ At the $\mathbf{E}$-point, $\boldsymbol{p H}=7.00$ (neutral)
To calculate the $\boldsymbol{p} \boldsymbol{H}$ during the titration:

1. Calculate the $\mathbf{m m o l}$ of $\mathbf{H}_{3} \mathbf{O}^{+}$from the acid
2. Calculate the $\mathbf{m m o l}$ of $\mathbf{O H}^{-}$from the base
3. Calculate the excess mmol of $\mathbf{H}_{3} \mathbf{O}^{+}$or $\mathbf{O H}^{-}$from the difference between (1) and (2)
4. Calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$or $\left[\mathrm{OH}^{-}\right]$from the excess and the total volume of the solution $\left(\boldsymbol{V}_{\text {tot }}\right) \rightarrow$ convert to $\boldsymbol{p H}$

Example: Calculate the $\boldsymbol{p} \boldsymbol{H}$ during the titration of $\mathbf{4 0 . 0} \mathbf{~ m L ~} \mathbf{0 . 1 0 0} \mathbf{M ~ H C l}$ with $\mathbf{0 . 1 0 0} \mathbf{M ~ N a O H}$ after the addition of $\mathbf{2 5 . 0} \mathbf{~ m L ~ N a O H}$.
$0.100 \mathrm{M} \mathrm{HCl} \rightarrow 0.100 \mathrm{M} \mathrm{H}_{3} \mathrm{O}^{+}=0.100 \mathrm{mmol} / \mathrm{mL}$
$0.100 \mathrm{M} \mathrm{NaOH} \rightarrow 0.100 \mathrm{M} \mathrm{OH}^{-}=0.100 \mathrm{mmol} / \mathrm{mL}$

1. $\mathbf{H}_{3} \mathbf{O}^{+} \rightarrow 40.0 \mathrm{~mL} \times 0.100 \mathrm{mmol} / \mathrm{mL}=\mathbf{4 . 0 0} \mathbf{~ m m o l}$
2. $\mathbf{O H}^{-} \rightarrow 25.0 \mathrm{~mL} \times 0.100 \mathrm{mmol} / \mathrm{mL}=\mathbf{2 . 5 0} \mathbf{~ m m o l}$
3. Excess acid $=4.00-2.50=\mathbf{1 . 5 0} \mathbf{~ m m o l ~} \mathbf{H}_{\mathbf{3}} \mathbf{O}^{+}$
4. $\boldsymbol{V}_{\text {tot }}=40.0+25.0=\mathbf{6 5 . 0} \mathbf{~ m L}$
$1.50 \mathrm{mmol} / 65.0 \mathrm{~mL}=\mathbf{0 . 0 2 3 1} \mathbf{M ~ H}_{3} \mathbf{O}^{+}$
$\boldsymbol{p} \boldsymbol{H}=-\log (0.0231)=\mathbf{1 . 6 4}$ (acidic, before E-point)

Example: Calculate the $\boldsymbol{p H}$ during the titration of $\mathbf{2 0 . 0} \mathbf{~ m L ~} \mathbf{0 . 5 0 0} \mathbf{M ~ H C l}$ with $\mathbf{0 . 2 5 0} \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ after the addition of $\mathbf{2 1 . 0} \mathbf{~ m L ~ B a}(\mathrm{OH})_{2}$
$0.500 \mathrm{M} \mathrm{HCl} \rightarrow 0.500 \mathrm{M} \mathrm{H}_{3} \mathrm{O}^{+}$
$0.250 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2} \rightarrow 0.500 \mathrm{M} \mathrm{OH}^{-}!!!$

1. $\mathbf{H}_{\mathbf{3}} \mathbf{O}^{+} \rightarrow 20.0 \mathrm{~mL} \times 0.500 \mathrm{mmol} / \mathrm{mL}=\mathbf{1 0 . 0} \mathbf{~ m m o l}$
2. $\mathbf{O H}^{-} \rightarrow 21.0 \mathrm{~mL} \times 0.500 \mathrm{mmol} / \mathrm{mL}=\mathbf{1 0 . 5} \mathbf{~ m m o l}$
3. Excess base $=10.5-10.0=\mathbf{0 . 5 0} \mathbf{~ m m o l} \mathbf{O H}^{-}$
4. $\boldsymbol{V}_{\text {tot }}=20.0+21.0=\mathbf{4 1 . 0} \mathbf{~ m L}$
$0.50 \mathrm{mmol} / 41.0 \mathrm{~mL}=\mathbf{0 . 0 1 2} \mathbf{~ M ~ O H}^{-}$
$\boldsymbol{p O H}=-\log (0.012)=\mathbf{1 . 9 1}$
$\boldsymbol{p} \boldsymbol{H}=14.00-1.91=\mathbf{1 2 . 0 9}$ (basic, after E-point)

Example: Calculate the $\boldsymbol{p} \boldsymbol{H}$ during the titration of $\mathbf{2 0 . 0} \mathbf{~ m L} \mathbf{0 . 5 0 0} \mathbf{M ~ H C O O H}$ with $\mathbf{0 . 5 0 0} \mathbf{M ~ N a O H}$ after the addition of $\mathbf{0 . 0}, \mathbf{1 0 . 0}, \mathbf{1 9 . 0}, \mathbf{2 0 . 0}$ and $\mathbf{2 1 . 0}$ $\mathbf{m L ~ N a O H}$

1) $\mathbf{0 . 0} \mathbf{~ m L ~ N a O H}$ added (Initial point):
$\rightarrow \mathrm{A} 0.500 \mathrm{M}$ solution of the weak acid HCOOH

| Example: Calculate the $\boldsymbol{p H}$ during the titration of $\mathbf{2 0 . 0} \mathbf{~ m L} \mathbf{0 . 5 0 0} \mathbf{M ~ H C O O H}$ with $\mathbf{0 . 5 0 0} \mathbf{~ M ~ N a O H}$ after the addition of $\mathbf{0 . 0}, \mathbf{1 0 . 0}, \mathbf{1 9 . 0}, \mathbf{2 0 . 0}$ and $\mathbf{2 1 . 0}$ $\mathbf{m L ~ N a O H}$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| 1) $\mathbf{0 . 0} \mathbf{~ m L ~ N a O H ~ a d d e d ~ ( I n i t i a l ~ p o i n t ) : ~}$ |  |  |  |  |
| $\rightarrow$ A 0.500 M solution of the weak acid HCOOH |  |  |  |  |
| $\mathrm{HCOOH}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{HCOO}^{-}$ |  |  | $K_{a}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right][\mathrm{HCOO}}{}{ }^{-}$ |  |
| i $\mathbf{0 . 5 0 0}$ | 0 | 0 |  |  |
| c-x | $+x$ |  |  |  |
| e 0.500-x |  | $x$ |  |  |
| $\boldsymbol{x}=\left(0.500 K_{a}\right)^{1 / 2}=\left(1.8 \times 10^{-4} \times 0.500\right)^{1 / 2}=9.5 \times 10^{-3}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ |  |  |  |  |
| $\Rightarrow \boldsymbol{p} \boldsymbol{H}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(9.5 \times 10^{-3}\right)=\mathbf{2 . 0 2}$ |  |  |  |  |

$>$ A titration curve for the titration of a strong base with a strong acid looks like a mirror image of that for the titration of a strong acid with a strong base

- Characteristics of strong acid-strong base $\mathbf{t}$-curves
- Slow $\boldsymbol{p H}$ changes before and after the $\mathbf{E}$-point
- A sharp $\boldsymbol{p H}$ change at the $\mathbf{E}$-point $(\boldsymbol{p H}=7.00) \rightarrow 1-2$ drops cause a $\boldsymbol{p} \boldsymbol{H}$ change of $5-6 \mathrm{pH}$ units)
- The vertical region of the $t$-curve is quite long (from $p H \approx 4$ to $p H \approx 10$ )
- Any indicator having a range within the vertical region of the $\mathbf{t}$-curve can be used (the indicator range does not have to be at 7.00)
$\Rightarrow$ Phenolphthalein (8.3-10), Methyl red (4.3-6.2), Phenol red (6.8-8.3), $\ldots$ can all be used

## Weak Acid-Strong Base Titration Curves

$>$ The strong base is completely converted to $\mathrm{OH}^{-}$in water solution
$\Rightarrow$ The net ionic equation of the titration is:

$$
\mathrm{HA}+\mathrm{OH}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{A}^{-}
$$

$\Rightarrow$ At the $\mathbf{E}$-point, $\boldsymbol{p H}>\mathbf{7 . 0 0}$ (basic) due to the presence of $\mathbf{A}^{-}$which is a weak base
Regions of the titration curve:

1. Initial point $\rightarrow$ solution of the weak acid HA
2. Before the E-point $\rightarrow$ buffer solution of the weak acid, HA, and its conjugate base, A- (buffer region)
3. At the $\mathbf{E}$-point $\rightarrow$ solution of the weak base $\mathbf{A}^{-}$
4. After the E-point $\rightarrow$ excess of $\mathrm{OH}^{-}$from base

| 2) $\mathbf{1 0 . 0} \mathbf{~ m L ~ N a O H ~ a d d e d ~ ( H a l f - w a y ~ t o ~ t h e ~ E - p o i n t ) : ~}$ |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $0.500 \mathrm{M} \mathrm{HCOOH} \quad 0.500 \mathrm{M} \mathrm{NaOH} \rightarrow 0.500 \mathrm{M} \mathrm{OH}^{-}$ |  |  |  |  |  |
| $\mathbf{H C O O H} \rightarrow 20.0 \mathrm{~mL} \times 0.500 \mathrm{mmol} / \mathrm{mL}=\mathbf{1 0 . 0} \mathbf{~ m m o l}$ $\mathbf{O H}^{-} \rightarrow 10.0 \mathrm{~mL} \times 0.500 \mathrm{mmol} / \mathrm{mL}=\mathbf{5 . 0 0} \mathbf{~ m m o l}$ |  |  |  |  |  |
|  |  |  |  |  |  |
|  $\mathrm{HCOOH}+\mathrm{OH}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HCOO}^{-}$ |  |  |  |  |  |
| - |  | 10.0 | 5.00 |  | 0.00 |
|  |  | -5.00 | -5.00 |  | +5.0 |
|  |  | 5.00 | 0.00 |  | 5.00 |
| $\rightarrow$ The system is a buffer ( $\left.\mathrm{HCOOH} \rightarrow \boldsymbol{a}, \mathrm{HCOO}^{-} \rightarrow \boldsymbol{b}\right)$ |  |  |  |  |  |
| $\boldsymbol{p} \boldsymbol{H}=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}+\log \left(\boldsymbol{n}_{\boldsymbol{b}} / \boldsymbol{n}_{\boldsymbol{a}}\right)=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}+\log (5.00 / 5.00)=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}+0$ |  |  |  |  |  |
| $\Rightarrow \boldsymbol{p H}=\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}=-\log \left(1.8 \times 10^{-4}\right)=\mathbf{3 . 7 4}$ |  |  |  |  |  |
| $\Rightarrow$ Half-way to the E-point $\rightarrow \boldsymbol{p H}=\boldsymbol{p} \boldsymbol{K}_{a}$ !!! |  |  |  |  |  |

3) $\mathbf{1 9 . 0} \mathbf{~ m L ~ N a O H}$ added (Before the E-point): $0.500 \mathrm{M} \mathrm{HCOOH} \quad 0.500 \mathrm{M} \mathrm{NaOH}^{\rightarrow} 0.500 \mathrm{M} \mathrm{OH}^{-}$ $\mathbf{H C O O H} \rightarrow 20.0 \mathrm{~mL} \times 0.500 \mathrm{mmol} / \mathrm{mL}=\mathbf{1 0 . 0} \mathbf{~ m m o l}$ $\mathbf{O H}^{-} \rightarrow 19.0 \mathrm{~mL} \times 0.500 \mathrm{mmol} / \mathrm{mL}=\mathbf{9 . 5 0} \mathbf{~ m m o l}$

|  |  | $\mathrm{HCOOH}+\mathrm{OH}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HCOO}^{-}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{~}$ | $\boldsymbol{s}$ | $\mathbf{1 0 . 0}$ | $\mathbf{9 . 5 0}$ | - | $\mathbf{0 . 0 0}$ |

## Weak base-Strong Acid Titration Curves

$>$ The strong acid is completely converted to $\mathrm{H}_{3} \mathrm{O}^{+}$in water solution
$\Rightarrow$ The net ionic equation of the titration is:

$$
\mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{B} \rightarrow \mathrm{HB}^{+}+\mathrm{H}_{2} \mathrm{O}
$$

$\Rightarrow$ At the $\mathbf{E}$-point, $\boldsymbol{p H}<\mathbf{7 . 0 0}$ (acidic) due to the presence of $\mathbf{H B}^{+}$which is a weak acid
Regions of the titration curve:

1. Initial point $\rightarrow$ solution of the weak base $B$
2. Before the E-point $\rightarrow$ buffer solution of the weak base, B , and its conjugate acid, $\mathrm{HB}^{+}$(buffer region)
3. At the E-point $\rightarrow$ solution of the weak acid $\mathbf{H B}^{+}$
4. After the E-point $\rightarrow$ excess of $\mathrm{H}_{3} \mathbf{O}^{+}$from acid

## Dependence of the Titration Curve on the Strength of the Acid or Base

- Weaker acids and bases have shorter vertical $\boldsymbol{p H}$ ranges at the E-point (more difficult to detect)

A titration curve for the titration of a weak base with a strong acid looks like a mirror image of that for the titration of a weak acid with a strong base

- Characteristics of $\mathbf{t}$-curves involving weak acids/bases
- Slow $\boldsymbol{p} \boldsymbol{H}$ changes before and after the $\mathbf{E}$-point and a sharp $\boldsymbol{p} \boldsymbol{H}$ change at the E-point
- At the E-point
- $\boldsymbol{p H} \boldsymbol{H} 7.00$ for titration of weak acids
$\cdot p \boldsymbol{H}<7.00$ for titration of weak bases
- Half-way to the E-point, $\boldsymbol{p} \boldsymbol{H}$ equals $\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a}}$ of the weak acid (or the conjugate acid of the weak base)
- The vertical region of the $\mathbf{t}$-curve is shorter than the vertical region for strong acid-strong base titrations
- A careful selection of the indicator is necessary

## Titration Curves for Polyprotic Acids

$>$ The loss of each proton results in a separate $\mathbf{E}$ point and a separate buffer region
$\rightarrow$ For a diprotic acid, $\mathrm{H}_{2} \mathrm{~A}$, titrated with a strong base there are two E-points and two buffer regions $>$ The net ionic equations of the titration are:

$$
\begin{array}{ll}
\mathrm{H}_{2} \mathrm{~A}+\mathrm{OH}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HA}^{-} & \left(1^{\text {st }} \text { E-point }\right) \\
\mathrm{HA}^{-}+\mathrm{OH}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{A}^{2-} & \left(2^{\text {nd }} \text { E-point }\right)
\end{array}
$$

Example: Titration of $\mathrm{H}_{2} \mathrm{SO}_{3}$ (a diprotic acid with $\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a} 1}=1.85$ and $\boldsymbol{p} \boldsymbol{K}_{\boldsymbol{a} \boldsymbol{2}}=7.19$ ) with NaOH

$$
\begin{array}{ll}
\mathrm{H}_{2} \mathrm{SO}_{3}+\mathrm{OH}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HSO}_{3}^{-} & \left(1^{\text {st }} \text { E-point }\right) \\
\mathrm{HSO}_{3}^{-}+\mathrm{OH}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{SO}_{3}^{2-} & \left(2^{\text {nd }} \text { E-point }\right)
\end{array}
$$

### 19.3 Equilibria of Slightly Soluble Ionic Compounds

- Slightly soluble ionic solids reach equilibrium with their saturated solutions at very low concentrations of the dissolved solute
- The dissolved portion of the ionic solid is assumed to be completely dissociated to ions (not always the case)

## The Solubility-Product Constant ( $K_{s p}$ )

$>$ For an ionic solid, $\mathrm{M}_{p} \mathrm{~A}_{q}$, in equilibrium with its saturated solution, the equilibrium constant of the dissolution process is called solubility-product

$$
\begin{gathered}
\mathrm{M}_{p} \mathrm{~A}_{q}(\mathrm{~s}) \leftrightarrow p \mathrm{M}^{m+}+q \mathrm{~A}^{n-} \\
\boldsymbol{K}_{s p}=\left[\mathbf{M}^{\boldsymbol{m +}}\right]^{p}\left[\mathbf{A}^{n-}\right]^{q}
\end{gathered}
$$

Example: Write the solubility-product expression for $\mathrm{Al}(\mathrm{OH})_{3}$.
$\rightarrow$ The subscripts in the formula become powers in the solubility-product expression

$$
\Rightarrow \quad \boldsymbol{K}_{s p}=\left[\mathrm{Al}^{3+}\right]\left[\mathrm{OH}^{-}\right]^{3}
$$

Sulfides are slightly different since $\mathrm{S}^{2-}$ acts as a strong base in water and converts entirely to $\mathrm{OH}^{-}$

## Example: $\mathrm{Ag}_{2} \mathrm{~S}$

$$
\begin{aligned}
& \mathrm{Ag}_{2} \mathrm{~S}(\mathrm{~s}) \leftrightarrow 2 \mathrm{Ag}^{+}+\mathrm{S}^{2-} \\
& \mathrm{S}^{2-}+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{HS}^{-}+\mathrm{OH}^{-} \\
\rightarrow & \mathrm{Ag}_{2} \mathrm{~S}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \leftrightarrow 2 \mathrm{Ag}^{+}+\mathrm{H} \\
\Rightarrow & \quad K_{s p}=\left[\mathrm{Ag}^{+}\right]^{2}\left[\mathrm{HS}^{-}\right]\left[\mathrm{OH}^{-}\right]
\end{aligned}
$$

Example: The solubility of $\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}$ is $0.022 \mathrm{~g} / \mathrm{L}$ at $25^{\circ} \mathrm{C}$. Calculate $\boldsymbol{K}_{\text {sp }}$ of $\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}$.
$\rightarrow$ Convert the solubility to molar solubility, $s$
$s=0.022 \frac{\mathrm{~g} \mathrm{~Pb}\left(\mathrm{IO}_{3}\right)_{2}}{\mathrm{~L}} \times \frac{1 \mathrm{~mol} \mathrm{~Pb}\left(\mathrm{IO}_{3}\right)_{2}}{557 \mathrm{~g} \mathrm{~Pb}\left(\mathrm{IO}_{3}\right)_{2}}=3.9 \times 10^{-5} \frac{\mathrm{~mol}}{\mathrm{~L}}$
$\rightarrow$ Express $\boldsymbol{K}_{\mathrm{sp}}$ through the molar solubility, $\boldsymbol{s}$

$$
\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}(\mathrm{~s}) \leftrightarrow \mathrm{Pb}^{2+}+2 \mathrm{IO}_{3}^{-}
$$

$1 \mathrm{~mol} \mathrm{~Pb}\left(\mathrm{IO}_{3}\right)_{2} \rightarrow 1 \mathrm{~mol} \mathrm{~Pb}^{2+}$
$1 \mathrm{~mol} \mathrm{~Pb}\left(\mathrm{IO}_{3}\right)_{2} \rightarrow 2 \mathrm{~mol} \mathrm{IO}_{3}^{-}$
$\Rightarrow\left[\mathrm{Pb}^{2+}\right]=\boldsymbol{s} \quad$ and $\quad\left[\mathrm{IO}_{3}^{-}\right]=2 \boldsymbol{s}$
$\Rightarrow \boldsymbol{K}_{\text {sp }}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{IO}_{3}^{-}\right]^{2}=\boldsymbol{s}(2 \boldsymbol{s})^{2}=4 \boldsymbol{s}^{3}$
$\Rightarrow \boldsymbol{K}_{\text {sp }}=4 \times\left(3.9 \times 10^{-5}\right)^{3}=2.5 \times \mathbf{1 0}^{-13}$
$>\boldsymbol{K}_{s p}$ can be used as a guide in comparing molar solubilities of different ionic compounds (works only if the compounds have the same number of ions in the formula)

$$
\uparrow \boldsymbol{K}_{s p} \Leftrightarrow \uparrow s
$$

Table 19.3 Relationship Between $K_{\text {sp }}$ and Solubility at $25^{\circ} \mathrm{C}$

| No. of lons | Formula | Cation:Anion | $\boldsymbol{K}_{\text {sp }}$ | Solubility $(\mathbf{M})$ |
| :---: | :--- | :---: | :---: | :---: |
| 2 | $\mathrm{MgCO}_{3}$ | $1: 1$ | $3.5 \times 10^{-8}$ | $1.9 \times 10^{-4}$ |
| 2 | $\mathrm{PbSO}_{4}$ | $1: 1$ | $1.6 \times 10^{-8}$ | $1.3 \times 10^{-4}$ |
| 2 | $\mathrm{BaCrO}_{4}$ | $1: 1$ | $2.1 \times 10^{-10}$ | $1.4 \times 10^{-5}$ |
| 3 |  |  |  |  |
| 3 | $\mathrm{Ca}(\mathrm{OH})_{2}$ | $1: 2$ | $6.5 \times 10^{-6}$ | $1.2 \times 10^{-2}$ |
| 3 | $\mathrm{BaF}_{2}$ | $1: 2$ | $1.5 \times 10^{-6}$ | $7.2 \times 10^{-3}$ |
| 3 | $\mathrm{CaF}_{2}$ | $1: 2$ | $3.2 \times 10^{-11}$ | $2.0 \times 10^{-4}$ |
|  | $\mathrm{Ag}_{2} \mathrm{CrO}_{4}$ | $2: 1$ | $2.6 \times 10^{-12}$ | $8.7 \times 10^{-5}$ |

- $\boldsymbol{K}_{s p}$ is a measure of the extent to which the solubility equilibrium proceeds to the right $\uparrow \boldsymbol{K}_{s p} \Leftrightarrow \uparrow$ Solubility
$-\boldsymbol{K}_{s p}$ depends on temperature

## Calculations Involving $\boldsymbol{K}_{s p}$

- Molar solubility ( $s$ ) - the molarity of the saturated solution (mol/L)
- The solubility is often expressed in $\mathrm{g} / \mathrm{L}$ or grams $/ 100 \mathrm{~mL}$ of solution $\rightarrow$ can be easily converted to $\mathrm{mol} / \mathrm{L}$
- $\boldsymbol{K}_{s p}$ can be experimentally determined by measuring the molar solubility, $\boldsymbol{s}$
$-\boldsymbol{s}$ can be calculated if $\boldsymbol{K}_{s p}$ is known

Example: The $\boldsymbol{K}_{\text {sp }}$ of $\mathrm{Ag}_{2} \mathrm{SO}_{4}$ is $1.4 \times 10^{-5}$ at $24^{\circ} \mathrm{C}$. Calculate the molar solubility of $\mathrm{Ag}_{2} \mathrm{SO}_{4}$.
$\rightarrow$ Express $\boldsymbol{K}_{s p}$ through the molar solubility, $\boldsymbol{s}$

$$
\mathbf{A g}_{2} \mathbf{S O}_{4}(\mathbf{s}) \leftrightarrow \mathbf{2 A g}^{+}+\mathbf{S O}_{4}{ }^{\mathbf{2 -}}
$$

$\Rightarrow\left[\mathrm{Ag}^{+}\right]=2 \boldsymbol{s} \quad$ and $\quad\left[\mathrm{SO}_{4}{ }^{2-}\right]=\boldsymbol{s}$
$\Rightarrow \boldsymbol{K}_{\text {sp }}=\left[\mathrm{Ag}^{+}\right]^{2}\left[\mathrm{SO}_{4}{ }^{2-}\right]=(2 \boldsymbol{s})^{2} \boldsymbol{s}=4 \boldsymbol{s}^{3}$
$\Rightarrow \boldsymbol{s}^{3}=\boldsymbol{K}_{\text {sp }} / 4 \quad \Rightarrow \quad \boldsymbol{s}=\left(\boldsymbol{K}_{\text {sp }} / 4\right)^{1 / 3}$
$\Rightarrow \boldsymbol{s}=\left(1.4 \times 10^{-5} / 4\right)^{1 / 3}=\mathbf{1 . 5} \times \mathbf{1 0}^{-2} \mathbf{M}$
Note: The problem can be solved using an ice table:
$\Rightarrow \boldsymbol{K}_{s p}=(2 \boldsymbol{s})^{2} \boldsymbol{s}=4 \boldsymbol{s}^{3}$

|  | $\mathrm{Ag}_{2} \mathrm{SO}_{4}(\mathrm{~s}) \leftrightarrow$ |  |  |
| :---: | :--- | :---: | :---: |
| $\boldsymbol{i}$ | excess | $\mathrm{Ag}^{+}+\mathrm{SO}_{4}{ }^{2-}$ |  |
| $\boldsymbol{c}$ | $-s$ | 0 | 0 |
| $e$ | excess | $+2 s$ | $+s$ |

## The Common Ion Effect

For a slightly soluble ionic solid, MA
$\mathrm{MA}(\mathrm{s}) \leftrightarrow \mathrm{M}^{n+}+\mathrm{A}^{n-} \quad \boldsymbol{K}_{\text {sp }}=\left[\mathrm{M}^{n+}\right]\left[\mathrm{A}^{n-}\right]$

- If $\mathrm{M}^{n+}$ is added by means of the soluble salt (MB), the equilibrium shifts to the left toward formation of more MA(s)
- MA and MB have a common ion ( $\mathrm{M}^{n+}$ )
- Similarly, if $\mathrm{A}^{n-}$ is added to the solution, the equilibrium also shifts to the left toward formation of more MA(s)
$\Rightarrow$ The molar solubility decreases in the presence of common ions

Example: At a given temperature, $\boldsymbol{K}_{s p}$ of AgBr is $7.7 \times 10^{-13}$. Estimate the solubility of AgBr in:
a) Pure $\mathrm{H}_{2} \mathrm{O}$
b) $0.10 \mathrm{M} \mathrm{CaBr}_{2}$ solution

## a) In pure $\mathrm{H}_{2} \mathrm{O}$

$\rightarrow$ Express $\boldsymbol{K}_{s p}$ through the molar solubility, $\boldsymbol{s}$

|  | $\mathrm{AgBr}(\mathrm{s}) \leftrightarrow \mathrm{Ag}^{+}+\mathrm{Br}^{-}$ |  |  |
| :---: | :---: | :---: | :---: |
| $\boldsymbol{i}$ | excess | 0 | 0 |
| $c$ | -S | +s | $+s$ |
| $e$ | excess | $S$ | S |

$\Rightarrow\left[\mathrm{Ag}^{+}\right]=\boldsymbol{s} \quad$ and $\quad\left[\mathrm{Br}^{-}\right]=\boldsymbol{s}$
$\Rightarrow \boldsymbol{K}_{\text {sp }}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Br}^{-}\right]=\boldsymbol{s}^{2}$
$\Rightarrow \boldsymbol{s}=\left(\boldsymbol{K}_{\text {sp }}\right)^{1 / 2}=\left(7.7 \times 10^{-13}\right)^{1 / 2}=\mathbf{8 . 8} \times 1 \mathbf{1 0}^{-7} \mathbf{M}$

## The Effect of $\boldsymbol{p H}$ on Solubility

$>$ The solubility of some ionic solids in water is greatly affected by the $\boldsymbol{p H}$

- Metal hydroxides $\left(\mathrm{Fe}(\mathrm{OH})_{3}, \mathrm{Mg}(\mathrm{OH})_{2}, \ldots\right)$ - the anion $\left(\mathrm{OH}^{-}\right)$reacts with added $\mathrm{H}_{3} \mathrm{O}^{+}$
$\Rightarrow$ The solubility can be improved by adding acids
Example: $\mathrm{Mg}(\mathrm{OH})_{2}$
$\mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s}) \leftrightarrow \mathrm{Mg}^{2+}+2 \mathrm{OH}^{-}$
$\rightarrow$ If acid $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$is added:
$\rightarrow \mathrm{H}_{3} \mathrm{O}^{+}$consumes $\mathrm{OH}^{-}\left(\mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-} \rightarrow 2 \mathrm{H}_{2} \mathrm{O}\right)$
$\rightarrow$ The equilibrium shifts to the right and the solubility increases

## b) In $0.10 \mathrm{M} \mathrm{CaBr}_{2}$ solution

$0.10 \mathrm{M} \mathrm{CaBr}_{2} \rightarrow 0.20 \mathrm{M} \mathrm{Br}^{-}$( $\mathrm{Br}^{-}$is the common ion)
$\rightarrow$ Express $\boldsymbol{K}_{s p}$ through the molar solubility, $\boldsymbol{s}$

|  | $\mathrm{AgBr}(\mathrm{s}) \leftrightarrow \mathrm{Ag}^{+}+\mathrm{Br}^{-}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{i}$ | excess | $\mathbf{0}$ | $\mathbf{0 . 2 0}$ |  |
| $\boldsymbol{c}$ | $-s$ | $+s$ | $+\boldsymbol{s}$ |  |
| $\boldsymbol{e}$ | excess | $\boldsymbol{s}$ | $\mathbf{0 . 2 0}+\boldsymbol{s}$ |  |

$\Rightarrow \boldsymbol{K}_{\text {sp }}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Br}^{-}\right]=\boldsymbol{s}(0.20+\boldsymbol{s})$
$\rightarrow$ Assume $\boldsymbol{s} \ll 0.20 \Rightarrow \boldsymbol{K}_{s p}=\boldsymbol{s}(0.20)$
$\Rightarrow \boldsymbol{s}=\boldsymbol{K}_{\text {sp }} / 0.20=7.7 \times 10^{-13} / 0.20=\mathbf{3 . 8} \times \mathbf{1 0}^{-12} \mathbf{M}$
$\rightarrow$ Check assumption $\rightarrow$ OK
$\Rightarrow$ The solubility is much lower in $0.1 \mathrm{M} \mathrm{CaBr}_{2}$

- Salts of weak acids $\left(\mathrm{CaCO}_{3}, \mathrm{BaSO}_{3}, \mathrm{PbF}_{2}, \mathrm{ZnS}\right.$, ...) - the anion of the salt is a weak base which reacts with added $\mathrm{H}_{3} \mathrm{O}^{+}$
$\Rightarrow$ The solubility can be improved by adding acids
Example: $\mathrm{BaSO}_{3}$ (a salt of $\mathrm{H}_{2} \mathrm{SO}_{3}$ )
$\mathrm{BaSO}_{3}(\mathrm{~s}) \leftrightarrow \mathrm{Ba}^{2+}+\mathrm{SO}_{3}^{2-}$
$\rightarrow$ If acid $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$is added:
$\mathrm{SO}_{3}{ }^{2-}+\mathrm{H}_{3} \mathrm{O}^{+} \rightarrow \mathrm{HSO}_{3}{ }^{-}+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
$\rightarrow \mathrm{H}_{3} \mathrm{O}^{+}$consumes $\mathrm{SO}_{3}{ }^{2-}$
$\rightarrow$ The equilibrium shifts to the right and the solubility increases
Example: $\mathrm{CaCO}_{3}(\mathrm{~s}) \leftrightarrow \mathrm{Ca}^{2+}+\mathrm{CO}_{3}{ }^{2-}$
$\mathrm{CO}_{3}{ }^{2-}+2 \mathrm{H}_{3} \mathrm{O}^{+} \rightarrow \mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$

Predicting Precipitation $-Q_{s p}$ versus $K_{s p}$
The reaction quotient of the dissolution process $\left(\boldsymbol{Q}_{s p}\right)$ is defined in the same way as $\boldsymbol{K}_{s p}$ and at equilibrium $\boldsymbol{Q}_{s p}=\boldsymbol{K}_{s p}$
To predict precipitation, compare $\boldsymbol{Q}_{s p}$ to $\boldsymbol{K}_{s p}$ $\rightarrow$ If $\boldsymbol{Q}_{s p}>\boldsymbol{K}_{s p}$, precipitation occurs
$\rightarrow$ If $\boldsymbol{Q}_{s p}<\boldsymbol{K}_{s p}$, dissolution occurs (no precipitation)
$\rightarrow$ If $\boldsymbol{Q}_{s p}=\boldsymbol{K}_{s p}$, no change occurs
Example: Does a precipitate form after mixing of $200 \mathrm{~mL} 1.0 \times 10^{-4} \mathrm{M} \mathrm{AgNO}_{3}$ with 900 . mL $1.0 \times 10^{-6} \mathrm{KCl}$ ?
( $\boldsymbol{K}_{\text {sp }}=1.8 \times 10^{-10}$ for AgCl$)$

```
\(\rightarrow\) Calculate \(\boldsymbol{Q}_{s p}\) :
    \(\boldsymbol{Q}_{s p}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]=\left(1.8 \times 10^{-5}\right) \times\left(8.2 \times 10^{-7}\right)\)
    \(\boldsymbol{Q}_{s p}=1.5 \times 10^{-11}\)
    \(\boldsymbol{K}_{\text {sp }}=1.8 \times 10^{-10}\)
    \(\Rightarrow \boldsymbol{Q}_{\text {sp }}<\boldsymbol{K}_{\text {sp }}\)
    \(\Rightarrow\) No precipitation occurs
```

$>$ In reality, the metal cation, $\mathbf{M}^{n+}$, is hydrated by several water molecules and the ligand, $\mathbf{L}$, gradually replaces them one at a time in stepwise manner

### 19.4 Equilibria Involving Complex Ions

- Complex ions - consist of a metal cation surrounded by anions or neutral molecules called ligands
- Complex ions are Lewis acid-base complexes (adducts)
- The metal cation is a Lewis acid
- The ligands are Lewis bases

## Formation of Complex Ions

$>$ For a metal cation, $\mathbf{M}^{\boldsymbol{n}}$, and a neutral ligand, $\mathbf{L}$, the complex formation is given by the equilibrium:

$$
\mathrm{M}^{n+}+m \mathrm{~L} \leftrightarrow \mathrm{M}(\mathrm{~L})_{m}{ }^{\mathrm{n}+}
$$

$$
\boldsymbol{K}_{f}=\frac{\left[\mathbf{M}(\mathbf{L})_{m}^{n+}\right]}{\left[\mathbf{M}^{n+}\right][\mathbf{L}]^{m}}
$$

$K_{f} \rightarrow$ formation constant of the complex

- Complexes between good Lewis acids (such as highly charged and transition metal cations) and good Lewis bases (such as $\mathrm{NH}_{3}, \mathrm{CN}^{-}, \mathrm{OH}^{-}, \ldots$ ) are extremely stable
- Their $\boldsymbol{K}_{f}$ values are very large ( $>10^{5}$ )
$\Rightarrow$ If enough ligand is present in the solution, almost the entire amount of the cation is converted to the complex $\rightarrow \boldsymbol{C}_{\boldsymbol{M}} \approx\left[\mathrm{M}(\mathrm{L})_{m}{ }^{n+}\right]$
Example: What is the concentration of $\mathrm{Fe}^{3+}$ after mixing of $\mathbf{2 5} \mathbf{m L} \mathbf{0 . 0 2 0} \mathbf{M ~ F e}\left(\mathrm{NO}_{3}\right)_{3}$ solution with $\mathbf{2 5} \mathbf{~ m L ~ 1 . 0 ~ M ~ K C N ~ s o l u t i o n ? ~}\left(K_{f}=\mathbf{4 . 0 \times 1 0} \mathbf{0}^{\mathbf{4 3}}\right.$ for the complex $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ )
$\rightarrow 0.020 \mathrm{M} \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3} \rightarrow 0.020 \mathrm{M} \mathrm{Fe}^{3+}$
$\rightarrow 1.0 \mathrm{M} \mathrm{KCN} \rightarrow 1.0 \mathrm{M} \mathrm{CN}^{-}$
$\rightarrow$ After mixing, the total volume is $25+25=50 \mathrm{~mL}$
$\Rightarrow \boldsymbol{C}_{\boldsymbol{F e}}=(0.020 \mathrm{M} \times 25 \mathrm{~mL} / 50 \mathrm{~mL})=0.010 \mathrm{M}$
$\Rightarrow \boldsymbol{C}_{C N}=(1.0 \mathrm{M} \times 25 \mathrm{~mL} / 50 \mathrm{~mL})=0.50 \mathrm{M}$

|  | $\mathrm{Fe}^{3+}+6 \mathrm{CN}^{-} \leftrightarrow \mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ |  |  | $K_{f}=\frac{\left[\mathrm{Fe}(\mathrm{CN})_{6}^{3-}\right]}{\left[\mathrm{Fe}^{3+}\right]\left[\mathrm{CN}^{-}\right]^{6}}$ |
| :---: | :---: | :---: | :---: | :---: |
| $i$ | 0.010 | 0.50 | 0 |  |
| c | $-x$ | -6x | + $x$ | 0.010 |
| $e$ | 0.010-x | 0.50-6x | $x$ | $K_{f}=\frac{0.010}{y(0.44)}{ }^{6}$ |
| $e$, | $y$ | 0.44 | 0.010 |  |

$\rightarrow \boldsymbol{K}_{f}$ is very large so almost the entire amount of
$\mathrm{Fe}^{3+}$ is converted to the complex
$\Rightarrow x \approx C_{F e} \quad \Rightarrow \quad x \approx 0.010$
$\Rightarrow(0.50-6 x) \approx(0.50-6 \times 0.010)=\mathbf{0 . 4 4}$
$\rightarrow$ Define a new variable, $\boldsymbol{y}=0.010-\boldsymbol{x}=\left[\mathrm{Fe}^{3+}\right]$

$$
\begin{aligned}
& K_{f}=\frac{0.010}{y(0.44)^{6}} \Rightarrow y=\frac{0.010}{K_{f}(0.44)^{6}} \\
& y=\frac{0.010}{4.0 \times 10^{43}(0.44)^{6}}=3.4 \times 10^{-44} \mathrm{M}=\left[\mathrm{Fe}^{3+}\right]
\end{aligned}
$$

Complex Ions and Solubility of Precipitates
$>$ The solubility of some ionic solids in water can be improved by the addition of an appropriate ligand (such as $\mathrm{NH}_{3}, \mathrm{CN}^{-}, \ldots$ )

- The ligand ( L ) forms a complex with the cation of the slightly soluble salt and the solubility equilibrium shifts toward further dissolution
$\mathrm{MA}(\mathrm{s}) \leftrightarrow \mathrm{M}^{n+}+\mathrm{A}^{n-} \quad \mathrm{M}^{n+}+m \mathrm{~L} \leftrightarrow \mathrm{M}(\mathrm{L})_{m}{ }^{\mathrm{n}+}$

Example: The solubility of AgCl can be improved by addition of ammonia, $\mathrm{NH}_{3}$. $\begin{array}{ll}\mathrm{AgCl}(\mathrm{s}) \leftrightarrow \mathrm{Ag}^{+}+\mathrm{Cl}^{-} & \boldsymbol{K}_{\text {sp }}=1.8 \times 10^{-10} \\ \mathrm{Ag}^{+}+2 \mathrm{NH}_{3}(\mathrm{aq}) \rightarrow \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+} & \boldsymbol{K}_{\boldsymbol{f}}=1.7 \times 10^{7}\end{array}$
$\oplus \rightarrow \mathrm{AgCl}(\mathrm{s})+2 \mathrm{NH}_{3}(\mathrm{aq}) \leftrightarrow \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}+\mathrm{Cl}^{-}$
$\rightarrow \boldsymbol{K}=\boldsymbol{K}_{s p} \times \boldsymbol{K}_{\boldsymbol{f}}=1.8 \times 10^{-10} \times 1.7 \times 10^{7}=\mathbf{3 . 1} \times \mathbf{1 0}^{-3}$
$\rightarrow$ The overall equilibrium constant, $\boldsymbol{K}$, is much larger than $\boldsymbol{K}_{s p}$
$\Rightarrow$ The addition of $\mathrm{NH}_{3}$ shifts the equilibrium to the right and the solubility increases
Example: Calculate the molar solubility of AgCl in $\mathbf{0 . 1 0} \mathbf{M ~ N H}_{3}$ solution.

Note: The solubility of AgCl in $0.10 \mathrm{M} \mathrm{NH}_{3}$ is higher than that in pure water which is:
$\boldsymbol{s}=\left(\boldsymbol{K}_{\text {sp }}\right)^{1 / 2}=\left(1.8 \times 10^{-10}\right)^{1 / 2}=\mathbf{1 . 3} \times \mathbf{1 0}^{-5} \mathbf{M}$

The solubility of amphoteric hydroxides can be explained as a complex formation process Example: $\mathrm{Al}(\mathrm{OH})_{3}$
$\rightarrow$ In acidic solution $\mathrm{OH}^{-}$ions are scarce so $\mathrm{Al}^{3+}$ is completely hydrated as $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$
$\rightarrow$ As the solution becomes less acidic and more basic, the $\mathrm{OH}^{-}$ions gradually accept $\mathrm{H}^{+}$from the hydrating water molecules
$\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}+\mathrm{OH}^{-} \leftrightarrow \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
$\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}+\mathrm{OH}^{-} \leftrightarrow \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(\mathrm{OH})_{2}{ }^{+}+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
$\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(\mathrm{OH})_{2}^{+}+\mathrm{OH}^{-} \leftrightarrow \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$

### 19.5 Applications of Ionic Equilibria Selective Precipitation

$>$ Mixtures of cations can be separated by selective precipitation with an anion if the solubilities of the precipitates are significantly different
$>$ The concentration of the anion is selected in a way so that $\boldsymbol{Q}_{s p}$ is above $\boldsymbol{K}_{s p}$ for the less soluble ion and just below $\boldsymbol{K}_{\text {sp }}$ for the more soluble ion
Example: What is the maximum concentration of $\mathrm{Cl}^{-}$that would precipitate only one of the ions in a solution that is $\mathbf{0 . 0 0 1 0} \mathrm{M}$ in $\mathrm{Ag}^{+}$and $\mathbf{0 . 0 2 0} \mathrm{M}$ in $\mathrm{Pb}^{2+} ? \boldsymbol{K}_{\text {sp }}(\mathrm{AgCl})=1.8 \times 10^{-10} ; \boldsymbol{K}_{\text {sp }}\left(\mathrm{PbCl}_{2}\right)=1.7 \times 10^{-5}$
$\mathrm{AgCl}(\mathrm{s}) \rightarrow \mathrm{Ag}^{+}+\mathrm{Cl}^{-} \quad \boldsymbol{K}_{s p}=\left[\mathrm{Ag}^{+}\right][\mathrm{Cl}]$
$\mathrm{PbCl}_{2}(\mathrm{~s}) \rightarrow \mathrm{Pb}^{2+}+2 \mathrm{Cl}^{-} \quad \boldsymbol{K}_{\text {sp }}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{Cl}^{-}\right]^{2}$
$\rightarrow$ Calculate the concentrations of $\mathrm{Cl}^{-}$at which precipitation of each ion begins:
$\left[\mathrm{Cl}^{-}\right]=\frac{K_{s p}}{\left[\mathrm{Ag}^{+}\right]}=\frac{\mathbf{1 . 8} \times 10^{-10}}{0.0010}=1.8 \times 10^{-7} \mathrm{M}$
$\left[\mathrm{Cl}^{-}\right]=\sqrt{\frac{K_{s p}}{\left[\mathrm{~Pb}^{2+}\right]}}=\sqrt{\frac{1.7 \times 10^{-5}}{\mathbf{0 . 0 2 0}}}=\mathbf{2 . 9 \times 1 0 ^ { - 2 } \mathrm { M } .}$
$\rightarrow \mathrm{AgCl}$ will precipitate first at $\left[\mathrm{Cl}^{-}\right]>1.8 \times 10^{-7} \mathrm{M}$ $\rightarrow$ If $\left[\mathrm{Cl}^{-}\right]<2.9 \times 10^{-2} \mathrm{M}, \mathrm{PbCl}_{2}$ will not precipitate $\Rightarrow$ The maximum [ $\mathrm{Cl}^{-}$] is just below $2.9 \times \mathbf{1 0}^{-\mathbf{2}} \mathbf{M}$
Note: The concentration of unprecipitated $\mathrm{Ag}^{+}$is:
$\left[\mathrm{Ag}^{+}\right]=\boldsymbol{K}_{s p} /\left[\mathrm{Cl}^{-}\right]=1.8 \times 10^{-10} / 2.9 \times 10^{-2}=6.2 \times 10^{-9} \mathrm{M}$
