### 18.5 Solving Problems Involving Weak Base Equilibria

- In a water solution of the weak base, B , there are two sources of $\mathrm{OH}^{-}$:

1. $\mathrm{B}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{HB}^{+}+\mathrm{OH}^{-}$(ionization of B )
2. $\mathrm{H}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-}$(autoionization)
$\rightarrow\left[\mathrm{OH}^{-}\right]_{1}=\left[\mathrm{HB}^{+}\right] \quad$ and $\quad\left[\mathrm{OH}^{-}\right]_{2}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$
$\rightarrow\left[\mathrm{OH}^{-}\right]=\left[\mathrm{OH}^{-}\right]_{1}+\left[\mathrm{OH}^{-}\right]_{2}=\left[\mathrm{HB}^{+}\right]+\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$
$\rightarrow$ If B is not very dilute or very weak, the autoionization can be neglected and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \ll\left[\mathrm{HB}^{+}\right]$

$$
\Rightarrow\left[\mathrm{OH}^{-}\right] \approx\left[\mathrm{HB}^{+}\right]=x
$$

$>$ Using equilibrium tables
$\rightarrow$ If he autoionization of water is neglected

|  |  |  | B + | HB | $\mathrm{OH}^{-}$ | $K_{b}=\frac{\left[\mathrm{HB}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\stackrel{+}{+}$ | $i$ |  | $C_{B}$ | 0 | 0 |  |  |
| 3 | c |  | -x | +x | + $\times$ |  | $x^{2}$ |
| 0 | $e$ |  | $C_{B}-x$ | $x$ | $x$ |  | $C_{B}-x$ |

$\rightarrow$ The quadratic equation can be solved for $x$ in order to determine $\left[\mathrm{OH}^{-}\right], \boldsymbol{p O H}$ and $\boldsymbol{p H}$
$\rightarrow$ If $\boldsymbol{x}$ is less than $5 \%$ of $\boldsymbol{C}_{\boldsymbol{B}}, \boldsymbol{x}$ can be neglected in the denominator ( $5 \%$ rule) $\rightarrow$ works if $\boldsymbol{C}_{B}$ is relatively large and $\boldsymbol{K}_{\boldsymbol{b}}$ is small $\left(\boldsymbol{C}_{\boldsymbol{B}} / \boldsymbol{K}_{\boldsymbol{b}}>400\right)$

$$
K_{b}=x^{2} / C_{B} \quad x=\left(K_{b} C_{B}\right)^{1 / 2}=\left[\mathrm{OH}^{-}\right]
$$

- In water solution, the weak base B exists in two forms $\rightarrow$ unionized (B) and ionized $\left(\mathrm{HB}^{+}\right)$

$$
\mathrm{B}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{HB}^{+}+\mathrm{OH}^{-}
$$

$\rightarrow \boldsymbol{C}_{\boldsymbol{B}}$ - total concentration of B
$\rightarrow C_{B}=[\mathrm{B}]+\left[\mathrm{HB}^{+}\right]$

$$
\Rightarrow[\mathrm{B}]=C_{B}-\left[\mathrm{HB}^{+}\right]=C_{B}-x
$$

$\rightarrow \mathrm{So}\left[\mathrm{OH}^{-}\right]=\boldsymbol{x},\left[\mathrm{HB}^{+}\right]=\boldsymbol{x},[\mathrm{B}]=C_{B}-\boldsymbol{x}$

$$
K_{b}=\frac{\left[\mathrm{HB}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]}=\frac{x^{2}}{C_{B}-x}
$$

The equation is equivalent to that for weak acids

## Finding $\boldsymbol{p H}$ Given $\boldsymbol{K}_{\boldsymbol{b}}$

Example: What is the $\boldsymbol{p} \boldsymbol{H}$ of a $\mathbf{0 . 1 0} \mathrm{M} \mathrm{NH}_{3}$ solution? $\left(\boldsymbol{K}_{\boldsymbol{b}}=\mathbf{1 . 8} \times \mathbf{1 0}^{-5}\right.$ for $\left.\mathbf{N H}_{3}\right)$

| [] | $\mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{NH}_{4}^{+}+\mathrm{OH}^{-}$ |  |  | $\boldsymbol{K}_{b}=\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{i}$ | 0.10 | 0 | 0 |  |
| $c$ | $-x$ | + $\times$ | $+x$ | $K_{L}=\boldsymbol{x}^{2}$ |
| $e$ | 0.10-x | $x$ | $x$ | $\boldsymbol{K}_{b}=\frac{x^{2}}{C_{N H_{3}}-\boldsymbol{x}}$ |
| $\rightarrow \boldsymbol{C}_{\text {NH3 }}=0.10 \rightarrow$ assume $\boldsymbol{x}<5 \%$ of $\mathbf{0 . 1 0}$ |  |  |  |  |
| $\Rightarrow \boldsymbol{x}=\left(K_{b} C_{N H 3}\right)^{1 / 2}=\left(1.8 \times 10^{-5} \times 0.10\right)^{1 / 2}=1.3 \times 10^{-3}=\left[\mathrm{OH}^{-}\right]$ |  |  |  |  |
| $\Rightarrow \boldsymbol{p O H}=-\log \left[\mathrm{OH}^{-}\right]=-\log \left(1.3 \times 10^{-3}\right)=2.87$ |  |  |  |  |
| $\Rightarrow \boldsymbol{p} \boldsymbol{H}=14.00-\boldsymbol{p O H}=14.00-2.87=\mathbf{1 1 . 1 3}$ |  |  |  |  |
| [Check assumption: $\left(1.3 \times 10^{-3 /} 0.10\right) \times 100=1.3 \%<5 \%$ ] |  |  |  |  |

## Extent of Base Ionization

- Percent ionization

$$
\mathrm{B}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{HB}^{+}+\mathrm{OH}^{-}
$$

$\rightarrow \boldsymbol{C}_{\boldsymbol{B}}=[\mathrm{B}]+\left[\mathrm{HB}^{+}\right] \quad \rightarrow \quad\left[\mathrm{HB}^{+}\right] \approx\left[\mathrm{OH}^{-}\right]$
$\rightarrow\left[\mathrm{HB}^{+}\right]=\boldsymbol{x}$ (ionized form of the base)
$\%$ ionized $=\frac{\left[\mathrm{HB}^{+}\right]}{C_{B}} \times 100=\frac{\left[\mathrm{OH}^{-}\right]}{C_{B}} \times 100=\frac{x}{C_{B}} \times 100$
$>$ For a given base, \% ionized decreases with increasing the total concentration of the base, $\boldsymbol{C}_{B}$

$$
\uparrow C_{B} \Leftrightarrow \downarrow \% \text { dissociation }
$$

## Anions of Weak Acids as Weak Bases

- The anion of the weak acid (HA) is its conjugate base ( $\mathrm{A}^{-}$)
- $\mathrm{A}^{-}$reacts as a weak base in water:

$$
\mathrm{A}^{-}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{HA}+\mathrm{OH}^{-} \quad \boldsymbol{K}_{b}=\frac{[\mathbf{H A}]\left[\mathbf{O H}^{-}\right]}{\left[\mathbf{A}^{-}\right]}
$$

- A- can be produced in solution by means of the soluble salt, MA, which dissociates completely: $\mathrm{MA}(\mathrm{s}) \rightarrow \mathrm{M}^{+}+\mathrm{A}^{-} \quad\left(\mathrm{M}^{+}\right.$is a spectator ion $)$
Example: For an aqueous solution of KF

$$
\begin{gathered}
\mathrm{KF}(\mathrm{~s}) \rightarrow \mathrm{K}^{+}+\mathrm{F}^{-} \\
\mathrm{F}^{-}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{HF}+\mathrm{OH}^{-} \\
\hline
\end{gathered}
$$

Example: Calculate the \% ionization for two $\mathrm{NH}_{3}$ solutions with concentrations $\mathbf{0 . 1 0}$ and $\mathbf{1 . 0} \mathrm{M}$. ( $\boldsymbol{K}_{b}=$ $\mathbf{1 . 8} \times \mathbf{1 0}^{-5}$ for $\mathbf{N H}_{3}$ )
$\rightarrow$ For the $\mathbf{0 . 1 0} \mathbf{M ~ N H}_{3}$ from the previous example:
$\boldsymbol{x}=\left(K_{b} C_{N H 3}\right)^{1 / 2}=\left(1.8 \times 10^{-5} \times 0.10\right)^{1 / 2}=1.3 \times 10^{-3}=\left[\mathrm{OH}^{-}\right]$
\% ionized $=\left(1.3 \times 10^{-3} / 0.10\right) \times 100=\mathbf{1 . 3} \%$
$\rightarrow$ For the $\mathbf{1 . 0} \mathrm{M} \mathrm{NH}_{3}$ similarly:
$\boldsymbol{x}=\left(K_{b} C_{N H 3}\right)^{1 / 2}=\left(1.8 \times 10^{-5} \times 1.0\right)^{1 / 2}=4.2 \times 10^{-3}=\left[\mathrm{OH}^{-}\right]$
\% ionized $=\left(4.2 \times 10^{-3} / 1.0\right) \times 100=\mathbf{0 . 4 2 \%}$
$\Rightarrow$ Increasing the concentration from 0.10 to 1.0 M
decreases the $\%$ ionized from 1.3 to $0.42 \%$
$>$ HA and $\mathrm{A}^{-}$are present in both, solutions of the weak acid HA, and solutions of its anion $\mathrm{A}^{-}$
Solutions of HA: $\mathrm{HA}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{A}^{-}$
Solutions of $\mathrm{A}^{-}: \quad \mathrm{A}^{-}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{HA}+\mathrm{OH}^{-}$
$>$ Both equilibria are shifted to the left so
$>$ Solutions of HA are acidic $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$and $[\mathrm{HA}] \gg\left[\mathrm{A}^{-}\right]$
$>$ Solutions of A- are basic $\left(\mathrm{OH}^{-}\right)$and $\left[\mathrm{A}^{-}\right] \gg$ [HA]
$>$ HA and $\mathrm{A}^{-}$are a conjugate acid base pair so
$\boldsymbol{K}_{\boldsymbol{a}}(\mathrm{HA}) \times \boldsymbol{K}_{\boldsymbol{b}}\left(\mathrm{A}^{-}\right)=\boldsymbol{K}_{\boldsymbol{w}} \quad \rightarrow \quad \boldsymbol{K}_{\boldsymbol{b}}\left(\mathrm{A}^{-}\right)=\boldsymbol{K}_{\boldsymbol{w}} / \boldsymbol{K}_{\boldsymbol{a}}(\mathrm{HA})$
$>$ Equilibrium calculations for $\mathrm{A}^{-}$are carried out using the same method as for the neutral base B

$$
K_{b}=\frac{[\mathrm{HA}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{A}^{-}\right]}=\frac{x^{2}}{C_{A^{-}}-x}
$$

Example: What is the $\boldsymbol{p H}$ of a $\mathbf{0 . 1 0} \mathrm{M} \mathrm{KF}$ solution? $\left(K_{a}=6.8 \times 10^{-4}\right.$ for HF)

| $\rightarrow \mathrm{KF}(\mathrm{s}) \rightarrow \mathrm{K}^{+}+\mathrm{F}^{-} \quad \rightarrow \boldsymbol{C}_{\boldsymbol{F}^{-}}=\mathbf{0 . 1 0} \mathrm{M}$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| [] | $\mathbf{F}^{-}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{HF}+\mathrm{OH}^{-}$ |  |  | $K_{b}=\frac{[\mathrm{HF}]\left[\mathrm{OH}^{-}\right.}{}$ |
| $i$ | 0.10 | 0 | 0 |  |
| $c$ | -x | +x | + $\times$ | ${ }^{2}$ |
| $e$ | 0.10-x | $x$ | $x$ | 0.10-x 0.10 |

$\rightarrow \boldsymbol{K}_{b}(\mathrm{~F})=\boldsymbol{K}_{\boldsymbol{w}} / \boldsymbol{K}_{a}(\mathrm{HF})=1.0 \times 10^{-14} / 6.8 \times 10^{-4}=1.5 \times 10^{-11}$
$\Rightarrow \boldsymbol{x}=\left(K_{b} \times 0.10\right)^{1 / 2}=\left(1.5 \times 10^{-11} \times 0.10\right)^{1 / 2}=1.2 \times 10^{-6}=\left[\mathrm{OH}^{-}\right]$
$\Rightarrow \boldsymbol{p O H}=-\log \left[\mathrm{OH}^{-}\right]=-\log \left(1.2 \times 10^{-6}\right)=5.92$
$\Rightarrow \boldsymbol{p H}=14.00-\boldsymbol{p O H}=14.00-5.92=\mathbf{8 . 0 8} \quad$ (basic)
[Check assumption: $\left(1.2 \times 10^{-6} / 0.10\right) \times 100=0.0012 \%<5 \%$ ]

Example: What is the $\boldsymbol{p} \boldsymbol{H}$ of a $\mathbf{0 . 1 0} \mathrm{M} \mathrm{NH}_{4} \mathrm{I}$ solution? $\left(\boldsymbol{K}_{\boldsymbol{b}}=\mathbf{1 . 8} \times \mathbf{1 0}^{-5}\right.$ for $\left.\mathrm{NH}_{3}\right)$
$\rightarrow \mathrm{NH}_{4} \mathrm{I}(\mathrm{s}) \rightarrow \mathrm{NH}_{4}^{+}+\mathrm{I}^{-} \quad \rightarrow \boldsymbol{C}_{\mathrm{NH}^{+}}=\mathbf{0 . 1 0} \mathbf{~ M}$

| [] | $\mathrm{NH}_{4}^{+}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{NH}_{3}$ |  |  | $K_{a}=\frac{\left[\mathbf{H}_{3} \mathbf{O}^{+}\right]\left[\mathbf{N H}_{3}\right]}{\left[\mathbf{N H}_{4}{ }^{+}\right]}$ |
| :---: | :---: | :---: | :---: | :---: |
| $i$ | 0.10 | 0 | 0 |  |
| c | -x | + $\times$ | $+x$ | ${ }^{2}$ |
| $e$ | 0.10-x | $x$ | $x$ | $\frac{x^{2}}{\mathbf{0 . 1 0 - x}} \approx \frac{x^{2}}{\mathbf{0 . 1 0}}$ |

$\boldsymbol{K}_{\boldsymbol{a}}\left(\mathrm{NH}_{4}^{+}\right)=\boldsymbol{K}_{\boldsymbol{w}} / \boldsymbol{K}_{\boldsymbol{b}}\left(\mathrm{NH}_{3}\right)=1.0 \times 10^{-14} / 1.8 \times 10^{-5}=5.6 \times 10^{-10}$
$\Rightarrow \boldsymbol{x}=\left(K_{a} \times 0.10\right)^{1 / 2}=\left(5.6 \times 10^{-10} \times 0.10\right)^{1 / 2}=7.5 \times 10^{-6}$
$\Rightarrow\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=7.5 \times 10^{-6} \mathrm{M}$
$\Rightarrow \boldsymbol{p} \boldsymbol{H}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(7.5 \times 10^{-6}\right)=\mathbf{5 . 1 3}$ (acidic)
[Check assumption: $\left(7.5 \times 10^{-6} / 0.10\right) \times 100=0.0075 \%<5 \%$ ]

Cations of Weak Bases as Weak Acids

- The cation of the weak base (B) is its conjugate acid ( $\mathrm{HB}^{+}$)
$-\mathrm{HB}^{+}$reacts as a weak acid in water:

$$
\mathrm{HB}^{+}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{B} \quad \boldsymbol{K}_{a}=\frac{\left[\mathbf{H}_{3} \mathbf{O}^{+}\right][\mathbf{B}]}{\left[\mathbf{H B}^{+}\right]}
$$

$>\mathrm{HB}^{+}$and B are a conjugate acid-base pair so

$$
\boldsymbol{K}_{\boldsymbol{a}}\left(\mathrm{HB}^{+}\right) \times \boldsymbol{K}_{\boldsymbol{b}}(\mathrm{B})=\boldsymbol{K}_{\boldsymbol{w}} \quad \rightarrow \quad \boldsymbol{K}_{\boldsymbol{a}}\left(\mathrm{HB}^{+}\right)=\boldsymbol{K}_{\boldsymbol{w}} / \boldsymbol{K}_{\boldsymbol{b}}(\mathrm{B})
$$

$>$ Equilibrium calculations for $\mathrm{HB}^{+}$are carried out using the same method as for the neutral acid HA

$$
K_{a}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right][\mathrm{B}]}{\left[\mathrm{HB}^{+}\right]}=\frac{x^{2}}{C_{H B^{+}}-x}
$$

### 18.6 Molecular Properties and Acid Strength

- Binary acids $\left(\mathrm{H}_{\mathrm{n}} \mathrm{X}\right)$ - consist of H and a second element, $\mathrm{X}\left(\mathrm{HF}, \mathrm{HCl}, \mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2} \mathrm{~S}, \ldots\right)$
$>$ Acid strength increases across a period (the $\boldsymbol{E N}$ of X increases $\rightarrow$ the $\mathrm{H}-\mathrm{X}$ bond becomes more polar $\rightarrow$ greater $\delta+$ charge on the $\mathrm{H} \rightarrow$ greater attraction of the H to the O atom of $\mathrm{H}_{2} \mathrm{O}$ )

$$
{ }^{\delta-\mathrm{X}-\mathrm{H}^{\delta+}----:}: \mathrm{OH}_{2} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{X}^{-}
$$

Example: $\mathrm{NH}_{3} \ll \mathrm{H}_{2} \mathrm{O}<\mathrm{HF}$
$>$ Acid strength increases down a group ( X becomes larger $\rightarrow$ the $\mathrm{H}-\mathrm{X}$ bond becomes longer and weaker $\rightarrow$ the $\mathrm{H}^{+}$comes off more easily)
Example: $\mathrm{HF} \ll \mathrm{HCl}<\mathrm{HBr}<\mathrm{HI}$

- Oxoacids $\left(\mathrm{H}_{\mathrm{n}} \mathrm{XO}_{\mathrm{m}}\right)$ - consist of $\mathrm{H}, \mathrm{O}$ and a third element, $\mathrm{X}\left(\mathrm{HClO}_{2}, \mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{H}_{3} \mathrm{PO}_{4}, \ldots\right)$
- The acidic H atoms are attached to O atoms
$>$ For oxoacids with the same \# of O atoms, acid strength increases with increasing the $E N$ of $X$ ( X withdraws electron density from the $\mathrm{O}-\mathrm{H}$ bond and makes it more polar $\rightarrow$ greater $\delta+$ charge on the $\mathrm{H} \rightarrow$ the $\mathrm{H}^{+}$comes off more easily)
Example: $\mathrm{HOI}<\mathrm{HOBr}<\mathrm{HOCl}$

$>$ For oxoacids having the same X , acid strength increases with increasing the \# of $O$ atoms (the high $\boldsymbol{E N}$ of O draws electron density from the $\mathrm{O}-\mathrm{H}$ bond and makes it more polar $\rightarrow$ greater $\delta+$ charge on the $\mathrm{H} \rightarrow$ the $\mathrm{H}^{+}$comes off more easily)
Example: $\mathrm{HClO}<\mathrm{HClO}_{2} \ll \mathrm{HClO}_{3}<\mathrm{HClO}_{4}$

$>$ Adding more $\boldsymbol{E N}$ atoms to the molecule increases the acidity further $\left(\mathbf{E x}: \mathrm{CH}_{3} \mathrm{COOH}<\mathrm{CF}_{3} \mathrm{COOH}\right)$

## Acidity of Hydrated Metal Ions

- Metal ions are hydrated in water solutions
- If the ion is small and highly charged ( $\mathrm{M}^{2+}$ or $\left.\mathrm{M}^{3+}\right)$, it draws electron density from the bound water molecules $\rightarrow \mathrm{H}^{+}$can be released $\rightarrow$ acidic
Example: $\mathrm{AlCl}_{3}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}+3 \mathrm{Cl}^{-}$

$$
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \leftrightarrow \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}+\mathrm{H}_{3} \mathrm{O}^{+}
$$
